Abiotic bioelectrodes for implantable glucose biofuel cells

On March 26, 2021, Myriam Ghodhbane defended a doctoral thesis from the Université Grenoble Alpes prepared under the supervision of the Professor Naceur Belgacem (Grenoble INP-Pagora/LGP2). She presented the results of her research entitled *Fabrication and optimization of abiotic bioelectrodes for implantable glucose biofuel cells*. This work aimed at optimizing the bioelectrode's manufacturing for implantable glucose biofuel cells using different coating technics.

An abiotic catalyst composed of graphene doped with iron and nitrogen was used to make biocathodes. Two deposition methods were used to fabricate two-dimensional biocathodes: ultrasonic spraying and doctor blade coating.

The biocathodes produced by ultrasonic spraying exhibited low current densities ($0.52 \mu\text{A} / \text{cm}^2$) due to the small amounts of active material deposited. The biocathodes produced by doctor blade coating – this method makes it possible to deposit larger quantities of material – have delivered current densities of $70 \mu\text{A} / \text{cm}^2$. These biocathodes have shown stability *in vitro* for two years. They were also implanted *in vivo* in a rat: a quasi-absence of inflammatory reaction and an ability to electro-catalyze oxygen were observed after five months of implantation.

The study then turned to the development of three-dimensional bioelectrodes. Abiotic biocathodes were produced by 3D printing, with a controlled macroporosity facilitating the diffusion of the substrate within the electrode. Two methods were applied: the use of the catalyst directly in the initial ink formulation and the creation of catalytic sites *in situ* in the 3D shape. To carry out this approach, the ink formulation and printing parameters have been optimized.

Maximum current densities of the order of $400 \mu\text{A} / \text{cm}^2$ were obtained by the first method. The second method improved electrochemical performance (factor 1.5). This can be explained by the increase in the conductivity as well as the porosity of the bioelectrodes due to the pyrolysis step. The biocathodes from the first method were assembled in hybrid biofuel cells and implanted in the intra-abdominal region of rats. This biofuel cells remained functional even after an implantation period of three months. Over this same period, a quasi-absence of inflammatory reaction was observed, highlighting the biocompatibility of the 3D-printed biocathodes.

Grenoble INP-Pagora, the international school of paper, print media and biomaterials. The school is Quality, Safety & Environment certified and part of Grenoble INP, an engineering and management institute geared towards training “engineers who are creative, responsible and committed to a sustainable world”. It trains engineers for the sectors of green chemistry, paper, printing, packaging, biomaterials and printed electronics. Its wide range of courses, pedagogical expertise and strong partnerships with industry allow it to continuously tailor its training to the needs of businesses and to the 60 graduates it produces each year, thus enabling them to embark upon stimulating careers in France and abroad. Grenoble INP-Pagora also develops international training: it offers a 2nd year engineering course, international semesters and a Biorefinery & Biomaterials Masters, taught in English. The innovative research performed by its LGP2 laboratory helps to improve processes and create products that meet all the latest requirements, notably those linked to the environment. These various activities ensure that the training offered is up to date with the latest scientific and technological advances. pagora.grenoble-inp.fr

The Laboratory of Pulp and Paper Science and Graphic Arts (LGP2) is a joint research unit (UMR 5518) run by the CNRS, Grenoble INP and the AGEFPI. It conducts its scientific activities in conjunction with the academic community of Grenoble Alpes University. LGP2 comprises three teams: *Biorefinery: chemistry and eco-processes* – *Multiscale biobased materials* – *Surface functionalization through printing processes*. Their research strives to meet society's expectations when it comes to sustainable development (green chemistry, clean processes, recycling, biobased materials, renewable energy) and traceability & safety (functional materials, smart paper and packaging). pagora.grenoble-inp.fr/lgp2

Finally, a study comparing two enzymatic anodes made from cellulose microfibrils (MFC) and chitosan demonstrated that the substitution of chitosan by MFC improves the anode electrochemical performance and kinetic constants.
